EASY-TO-OPEN COVERSField of the Invention

The invention relates to overcapping covers of bottles of sparkling wine, typically champagne, and in particular covers provided with easy-to-open means.

5 Background art

So-called easy-to-open covers, such as those in figures 1 to 5, are already known. Typically there are two types of covers: those with a tear strip often called a "Tircell" shown in figures 1 to 3, and those
10 with a single or double dashed or dotted line of weakness shown in figures 4 to 5.

Problems posed

The easy-to-open systems that have been proposed
15 previously pose a certain number of problems described below, irrespective of the system used.

As explained above the covers are applied typically to champagne bottles and they play a considerable role in the decorative aspect of the
20 bottles and improve their appearance.

When consumers open the cover either by pulling on the Tircell strip or cutting the cover along the dashed or dotted lines they invariably either fold or accidentally tear the cover. This is because the covers
25 are made of relatively thin sheets or films and the covers are not necessarily torn along the intended lines of weakness that are traced out in advance. The tearing may thus lead an unattractive appearance that is totally random.

09831918-020709

Sparkling wines are also put into bottles that are often provided with cork wire that ensures the cork remains in place and the bottle remains sealed even in the event of excess pressure being applied. It is therefore necessary for the cover to free the cork and cork wire (if present) when it is removed.

In other words an easy-to-open cover is required that overcomes all these drawbacks.

10 Aim of the invention

The invention relates to a cover that enables the user to remove its upper part, which is that covering said cork wire, in a single movement without damaging any of the lower part covering the section of the neck of the bottle beneath the cork wire, such that the maximum quantity of cover remains on the bottle in its attractive, undamaged condition while enabling the cork to be removed.

20 Description of the invention

According to the invention the easy-to-open overcapping cover 1, which is typically conical, comprises a head 5 and a skirt 4 of a film or sheet material, typically for a recipient or bottle of sparkling wine 2 sealed with a cork 8 with a head 80 with means for fastening the cork to the neck of said recipient, typically a metal cork wire 3 provided with a tightening wire 30 that goes under the glass ring 20 of the neck of said bottle and constitutes an opening twist or loop 31, or possibly for a recipient or bottle of still wine comprising easy-to-open means, typically a line of weakness, on the skirt of said cover, and is characterized in that:

09831918-020702

5 a) said easy-to-open means comprise at least one so-called line of weakness 44, described as being lower, located on the cover at a height H that defines a partition of said cover with a so-called upper part 10 and a so-called lower part 11; the height is such that after said cover and said recipient or sealed bottle have been assembled said line of weakness 44 breaks when said recipient or said bottle is first opened to provide access to said cork or possibly said cork wire once said upper part 10 has been removed, said lower part 11 remaining intact on the neck,

15 b) said upper part 10 comprises a gripping tab 46 the upper and lower ends of which include notches or recesses 460, 461 intended to direct the tearing of a tear strip 45 during said first opening,

20 c) said cover comprises at least one additional means selected from one of the following: a second so-called upper line of weakness 43 in said upper part 10, means 67 for reinforcing all or part of said lower part 11, means 66 for fastening all or part of said lower part 11 to the neck, means for reinforcing all or part of said upper part 10 such that when said recipient or bottle is opened for said first time said tear strip 45, which is created by pulling on gripping tab 46, removes the whole of said upper part 10 along with it, the lower edge of said strip being constituted when said line of weakness 44 breaks.

25 Height H is typically between 15 and 50 mm for recipients or bottles of sparkling wine and between 5 and 25 mm for recipients or bottles of still wine.

30 When covers are intended to overcap recipients or bottles of sparkling wine said fastening means may also consist of a staple hooked under the glass ring of the

09831918.020702

neck or a threaded cap that operates in conjunction with a threaded ring.

When the fastening means comprise a cork wire provided with an opening twist the line of weakness
5 should be located at such a height that when the cover is applied to said neck it is slightly below the opening twist under the glass ring.

The situation is similar when the fastening means comprise a staple because the ends of the staple,
10 similarly to the opening twist, hook under the glass ring that constitutes a contracted circular section.

The fastening means may consist of a threaded glass ring that operates in conjunction with a cap with a threaded skirt. In this configuration the line of
15 weakness is located just below the lower end of said threaded skirt.

Tests performed on covers of the invention and the background art have shown clearly the benefits of combining the means described above in a), b) and c).
20 The applicant has therefore taken advantage of these means to realize the aim in question, i.e. to remove the entire upper part of the cover in a single movement by pulling between the thumb and index finger of one hand while the other holds the bottle without damaging
25 the lower part of the cover and decoration.

The cover of the invention therefore enables the cover to be opened correctly under "standard" opening conditions. "Opened correctly" implies removing the upper part of the cover while leaving the lower part
30 intact, with a dividing line between the two parts that is typically a circle, such that the neck of the bottle remains covered with the lower part of the cover and said cover remains attractive.

04831918.020700

Tests performed on covers of the invention and the background art have shown clearly that the invention alone enables the cover to be removed correctly and repeatedly without the consumer having to be particularly careful when opening the cover, as is usually the case.

It is important to realize how covers behave when they are opened under "standard" conditions which are typically in social occasions when the person opening the bottle is talking to somebody or in any event is not particularly looking at the cover of the bottle to be opened.

It is under these "standard" conditions that the cover of the invention is of particular interest. Covers of the background art are only opened correctly provided the "Tircell" or the tear strip is pulled in a direction that always remains perpendicular to the axis of the bottle. This is only possible if great care is taken otherwise the "Tircell" does not follow the tear lines and the part of the skirt is torn that should not be or the upper part of the skirt is not correctly torn to reveal the cork wire. The problem is therefore resolved by the combination of the means described in a), b) and c).

Description of the figures

Figures 1 to 5 are partial lateral views of covers 1 of the background art obtained by rolling an arc of a skirt and bonding axial edges 60, 61 and showing various easy-to-open means located on skirt 4.

In figures 1 to 3 the easy-to-open means are "Tircell" strips 41 one end of which is oriented in a more or less sloping direction.

09831918.020702

In figure 4 the means is a double line of weakness 42 and in figure 5 a single line 40.

In principle these means enable upper part 10 of cover 1 to be removed and leave lower part 11 on the bottle.

Figure 6 is a side view of a conical cover 1 according to an embodiment of the invention.

Figures 6a and 6b relate to the upper part of covers 1 that constitute overcapping caps for bottles 2 of still wines sealed with a cork stopper. Figure 6a is a schematic cross-section along the vertical axis and figure 6b is a perspective side view in which opening tab 46 is shown positioned between the upper 43 and lower 44 lines of weakness, said lower line of weakness being located on glass ring 20 of bottle 2, skirt 4 of the cover being crimped under glass ring 20.

Figure 7 is a side view of a neck 7 of a bottle provided with a cover 1 of the invention where tab 46 is shown in the unfolded position ready to be gripped by the consumer, the tab before the cover is opened being folded back and flat against the cover as shown by the dotted line in the figure such that it does not extend beyond the rest of the cover and risk being pulled accidentally.

Figure 8 is a similar side view to that of figure 7 once the consumer has pulled tab 46 to create opening strip 45 and thus revealed cork wire 3 comprising a tightening wire 30 that goes under the glass ring and a tightening loop 31.

Figure 9 shows the result obtained after said cover has been opened easily, upper part 10 of the cover comprising head 5 remaining fastened to opening strip 46.

In figures 15a and 15b upper line of weakness 430
5 is partial such that head 5 is fastened to opening
strip 45 as illustrated in figure 9.

Figure 16 is a top view of the inner surface of an
arc 6 of conical skirt 4 of the cover consisting of a

film or sheet material the outer surface of which is generally printed or decorated, used to produce said cover and including:

5 - two upper 430 and lower 44 lines of weakness ending in notches 460, 461 along the axial edge 60 that constitutes the upper edge after said arc has been rolled, and a checkered tab 46, lower line of weakness 44 defining an upper part 69 and a lower part 65 of height H", upper line of weakness 430 being a partial
10 line that does not describe a full circle such that head 5 remains fastened to opening strip 45,

 - an upper reinforcement 47 of width L positioned between the two line of weakness 43 and 44, one end of which 472 constitutes a reinforcement of tab 46.

15 Arc 6 of height 'H' has an upper rim 64 to which the head of the cap and a lower part 65 of height H" are fastened.

 Figures 17a to 21b are similar to figure 16 and show other embodiments of the invention.

20 In figure 17a upper reinforcement 47 consists of two strips, each one being near a line of weakness 43, 44.

 In figure 17b upper reinforcement 47 comprises a thin strip or line of plastic material positioned along
25 lines of weakness 43, 44 and along tab 46.

 In figure 18a, only line of weakness 44 is present. An end 472 of upper reinforcement 47 extends beyond said gripping tab, said end acting as a gripping tab, upper reinforcement 47 extending along lower line
30 of weakness 44. Upper notch 460 is used to start the tearing of the upper part and to direct said tearing such that it is stopped by the other end of the upper

20250-016700

In this figure lower part 65 of arc 6 comprises a reinforcement strip coated with an adhesive
5 reinforcement 68 that can be activated.

In figure 19a upper reinforcement 47 consists of a row of strips or lines 48 of plastic material or varnish that extend from one line of weakness 43 to the other 44. Arc 6 has a lower reinforcement 67 that also consists of a strip or line.

In figure 20a, part of which is similar to figure 17a, the upper reinforcement has an end 472 that extends beyond said tab 46 as in figure 18a, lower part 65 having a part 66 coated with a layer of adhesive that can be activated.

Figures 21a to 21d are of various types of tabs 46 of the invention.

Detailed description of the invention

According to a first embodiment of the invention the cover may comprise, as an additional means, a so-

called second line of weakness 43 all or part of which is separated towards the top of the so-called lower line by a distance L at least equal to $0.5 H$, H being the height between the so-called lower line and the upper or top end of said cover 1, lines of weakness 43, 44 that define an opening strip 45 of width L .

Advantageously, said line of weakness may not extend around the entire periphery of the cover and constitutes a partial line of weakness 430 such that head 5 of the cover remains fastened to opening strip 45. Partial line of weakness 430 extends at an angle α that ranges typically between 240° and 320° .

Gripping tab 46 is typically positioned along a generating line of said cone and is located between two lines of weakness 43, 44 and fastened to said opening strip 45, said tab 46 using said notches 460, 461 to automatically direct the tearing strain when said cover is opened towards said two lines of weakness such that said cover is opened easily, ensuring the remaining lower part 11 of the cover located beneath said lower line 44 stays intact and said cork wire 3, if fitted, is freed. Figures 21a to 21d are of various types of tabs 46 of the invention.

Said tab 46 may comprise notches or recesses 460, 461 made in said film or sheet material constituting said cover, said notches constituting the means to direct the tearing strain of said strip 45.

Typically width L_1 of said tab 46 ranges from $0.5 L$ to L with L ranging between 1.5 and 4 cm.

All the figures of covers of the invention (figures 6 to 20) include a tab 46 that has an upper notch 460 and a lower notch 461 running along its edges in the axial direction.

09831918-020702

In most of these figures the covers or arcs of the covers comprise a so-called second upper line of weakness 43 all or part of which is separated from the top of the so-called lower line by a distance L at least equal to 0.5 H.

Figure 18a, however, shows a cover comprising a single line of weakness 44 whereas figure 11b shows a cover comprising only two lines of weakness without any additional means.

Figure 18b shows a cover comprising a tab of increasing width.

In a second embodiment of the invention the cover may comprise, as an additional means, means for reinforcing lower part 11, 65. Said means may consist of a lower reinforcement 67 that increases the mechanical properties of all or part of said lower part 11 and adheres to all or part of the inner surface of said lower part 11, 65 at least along said lower line of weakness 44 and parallel to said lower line of weakness, said lower reinforcement 67 may also comprise an adhesive layer that can be activated over all or part of the surface that is intended to adhere to said neck.

This embodiment is shown in figures 12b, 14a, 14b, 15b, 17b, 18a, 19a, 19b, 20a and 20b.

The entire lower reinforcement 67 may comprise a layer that can be activated and constitutes a circular strip 68 the width of which is at least equal to 5 mm and that can extend over all or part of the height of said lower part 11 and that is adjacent to at least the upper edge of said lower part 11 along and parallel to said lower line of weakness 44.

This embodiment is shown in figure 14a.

04481918-020702

5

10

15

20

25

30

Said upper reinforcement means 47 may comprise a lateral end 472 that reinforces all or part of said gripping tab 46. Said lateral end 472 may extend beyond said gripping tab such that said lateral end 472
 5 assumes the role of said gripping tab when the cover is first opened, as shown in figures 18a and 20a.

Reinforcement means 47 may comprise a reinforcement strip or line that has a lower edge 471 adjacent to at least lower line of weakness 44.

10 Figures 13a, 13b, 16, 18b, 20b show configurations in which the upper reinforcement is a strip that covers and reinforces the inner surface of opening strip 45.

Figures 12a, 12b, 17a, 17b, 18a, 19b and 20a, on the other hand, show various types of reinforcement
 15 strips certain of which are only adjacent to the lower line of weakness (figures 12a, 12b, 14b) and constitute a very thin line 48, as shown in figures 12b and 14b.

Said reinforcement means 47 may comprise an upper part or edge 470 that may or may not belong to the same reinforcement strip or line, said upper 470 and lower
 20 471 edges being separated by a width L, that is constant or otherwise depending on angular position α , width L ranging typically between 0.4 and 4 cm, average width L being preferably between 0.3 and 0.7 times H, H
 25 being the height between the so-called lower line and the upper end or top of said cover 1.

Figures 12a to 13a and 16 to 20b are non-limitative examples of the very wide range of reinforcement means 47 possible according to the
 30 invention.

As illustrated in figures 13b and 18b, width L is not necessarily constant and increases, typically regularly, with the angular position α , width L being

09831948:000000

According to different versions, said upper reinforcement means 47 may cover the entire interior surface (see figures 13a, 13b, 16, 18b, 20b) or inner periphery of the free part of said opening strip 45 (see figures 17a, 17b, 19b, 20a).

Figures 11a to 20b (except figure 11b) show various combinations of additional means.

20 According to the invention said upper 47 or lower
67 reinforcement means may consist either of a thin
sheet or reinforcement strip, typically of a plastic
material (preferably PET or PP), paper, or a layer,
strip or line of plastic, resin, varnish or paint
25 material and generally of any means that provide a
localized increase in the mechanical characteristics
and enable the objectives of the invention to be
realized.

According to the invention the material
30 constituting said cover may be selected from sheets or
strips of Al or Al alloys, Sn or Sn alloys, shrinkable
plastic, Al/PO/Al complex multilayers, Al/PO/paper,
PO/Al/PO, charged PO/Al/PO, where Al refers to a layer

The thickness of said material in sheets or strips may range between 25 and 50 μm when the material is aluminum or an alloy, between 110 and 150 μm when the material is tin or an alloy, between 60 and 100 μm when the material is a shrinkable plastic film and between 60 and 110 μm when the material is a complex multilayer material, typically Al/PO/Al.

- a blank of arc 6 of said skirt is cut out of said film or sheet material of height H',

- said additional means are provided, being selected from said upper line of weakness 43, said upper reinforcement means, said lower reinforcement means,

- a radial line of heat- or pressure-activated adhesive 63 is applied, typically on the other axial edge 61 of said arc, except on the part matching or opposite said tab 46,

- said arc 6 is rolled on a chuck by folding axial edge 60 back onto the other axial edge 61, a line of adhesive is applied between the two edges, or said pre-applied radial line of adhesive is activated, to shape said skirt 4 by pressing edges 60,61 together and possibly creating said grooves 9, and a head 5 is assembled or created, possibly by adding a part of the head and fastening it typically by thermobonding to

upper rim 64 of said skirt that is possibly shrunk and folded.

Figures 11 to 20b show arcs 6 of the invention before they are rolled.

5 In the method of the invention the upper or lower reinforcement can be deposited either by bonding a strip or part of a strip 47 with the mechanical characteristics required, which are typically resistance to tearing, and of a required shape, which
10 is typically part of an annular sector, or by using a gun to apply a strip or line 48 of melted plastic material that is adherent and that hardens when applied.

According to the invention said upper and lower
15 reinforcement means may be a self-adhesive label of suitable shape applied to said arc 6.

The method of the invention can be perfectly integrated into the standard methods used to shape covers by rolling arcs and it therefore constitutes a
20 method that is just as economical and productive as the standard method.

A further aim of the invention relates to the use of a cover of the invention as an overcapping cap for still wines. Once the measurements of the covers of the
25 invention have been suitably modified they may be used to overcap bottles of still wines, which are typically sealed with a cork, without or without a head. In this configuration the covers do not generally include grooves 9 and said additional means is preferably a
30 second line of weakness 43.

Lower line of weakness 44 is preferably located on glass ring 20, which is specific to bottles of still wine.

2025 RELEASE UNDER E.O. 14176

Examples of embodiments

Conical covers 1, such as that in figure 6, have been have been produced by rolling arcs as shown in figures 15a (test 1) and 15b (test 2) according to the method described above.

The cover in figure 6 comprises a skirt 4 and a head 5 with two lines of weakness: an upper line 43 and a lower line 44 separated from each other by a distance L of 30 mm, lower line 44 defining the upper or separable part 10 of the cover and the lower or fixed part 11 of the cover. The cover is shaped by rolling an arc 6 of a skirt according to figure 11a and thermobonding or bonding an axial edge 60 to the other edge 61 (not shown in figure 6). A dotted line shows line of adhesive 63 that seals the two edges together.

Before the cover is rolled lines of weakness 43, 44 and notches 460, 461 that define said 46 are created, the bottom of each notch 460, 461 being located on the corresponding line of weakness 43, 44. As shown in figures 6 and 11a, said tab 46 is checkered, i.e. provided with a lattice-work of small scores obtained by stamping when said arc and notches are cut out, in order to differentiate the tab visually and in terms of its appearance and to reinforce the visual contrast between the tab and the rest of the cap to encourage the consumer to use said tab 46 immediately in order to open the cover.

Upper part 10 of the skirt is provided with a row of grooves 9 that have both a visual and a technical function as they can enable line of weakness 44 to be broken cleanly without tearing lower part 11 of the skirt accidentally.

09031918 020702

The inner surface of lower part 11 of the skirt is coated with an annular layer of adhesive 66 that is activated when the cover is applied to the neck and is shown by a dotted line at height H_1 in figure 6.

5 The measurements of the produced covers are given in figure 6 with namely:

- $L = 30 \text{ mm}$,
- $H = 43 \text{ mm}$,

10 The width L_1 of the checkered tab shown in figure 6 is 25 mm.

The angle at the bottom of notches 460, 461 was selected as 75° .

15 The conicity of cover 1 is 6° , i.e. the angle formed by the oblique surfaces of skirt 4 shown in figure 6.

The measurements of arcs 6 in figures 11, 15a and 15b are:

- $H' = 130 \text{ mm}$
- $H'' = 80 \text{ mm}$

20 Test 1:

A $40 \text{ }\mu\text{m}$ -thick strip of aluminum was used as a material the outside surface of which was decorated with a gold-colored varnish.

25 Cover arcs 6 were shaped according to figure 15a by applying a layer of widely available, water-activated adhesive to a height H_1 equal to 5mm using screen printing techniques.

Test 2:

30 A $68 \text{ }\mu\text{m}$ -thick strip of Al/PE/Al complex material was used the outer surface of which was decorated with a gold colored varnish.

A reel consisting of a strip support was loaded with self-adhesive paper labels of a suitable shape and

20250101 09:07:03

height H_3 of 25 mm. The labels were then transferred to the blanks of arcs 6.

Test 3:

This test is similar to test 2. It differs in
5 that a reel consisting of a strip support was loaded with self-adhesive paper labels coated with a layer of widely available, water-activated adhesive.

Other tests:

Covers similar to the above were also produced in
10 30 μ m-thick strips of corrugated aluminum but that also comprised an upper reinforcement 47 for said upper part 10 that was positioned just above so-called line of weakness 44.

In a first embodiment, such as that shown in
15 figures 12a, 17a, 18a and 20a, upper reinforcement 47 consists of a PE-based black strip that adheres to the sheet of aluminum and is typically 5 mm wide, said strips running along line(s) of weakness 43, 44.

In a second embodiment, such as that shown in
20 figure 12b, 14b, 17b, 19a or 19b, upper reinforcement 47 is provided by applying a "hot-melt" type of resin line 48 using an application gun containing melted resin that solidifies when it comes into contact with the sheet of aluminum.

25 According to one version of this embodiment a line of resin is applied that is quick drying when exposed to ultraviolet rays.

In a third embodiment, such as that shown in
30 figures 13a, 13b, 16, 18b, 20b, said upper reinforcement 47 is provided by a strip that is typically self-adhesive and that covers the inner surface of opening strip 45 and that is more or less the same width L as said opening strip.

the invention was always intact whereas the same could not always be said of the bottles provided with covers of the background art.

5 Advantages of the invention

The invention has the double advantage of, on the one hand, overcoming the drawbacks of easy-to-open covers for sparkling wines by enabling the entire upper part 10 of the cover to be removed in a single movement by one hand while the other holds the bottle, and, on the other, to enable covers to be produced without requiring considerable modifications in the standard production methods. The invention also discloses a great many embodiments that can set off certain aspects 15 of the easy-to-open cover to advantage and therefore provides covers with a technical performance level that meets customers' requirements.
